Outbreak Alert! 2006 was researched and written by Caroline Smith DeWaal, Kendra Johnson, and Farida Bhuiya. We gratefully acknowledge the assistance of Michael F. Jacobson in preparing this report. We also thank the scientists in government public health agencies who provided information and inspiration for this report.

Center for Science in the Public Interest (CSPI) is a non-profit organization based in Washington, DC. Since 1971, CSPI has been working to improve the public’s health, largely through its work on nutrition and food-safety issues. CSPI is supported primarily by the 900,000 subscribers to its Nutrition Action Healthletter and by foundation grants.

EXECUTIVE SUMMARY

In the United States, foodborne illness has been estimated to cause 5,000 deaths and 76 million illnesses per year. Responsibility for food safety is divided among at least a dozen federal agencies involved in monitoring, surveillance, inspection, enforcement, outbreak management, research, and education. Despite recent improvements, significant gaps in the federal food-safety structure continue to put consumers at risk. To help fill one of these gaps, the Center for Science in the Public Interest (CSPI) maintains a database of foodborne illness outbreaks that have been linked to specific foods.

Findings
CSPI tracked a total of 5,000 foodborne illness outbreaks, involving 152,097 individual cases that occurred between 1990 and 2004. The food categories most commonly linked to foodborne illness outbreaks were:

- Seafood and seafood dishes: 984 outbreaks involving 9,969 cases of illness
- Produce and produce dishes: 639 outbreaks involving 31,496 cases of illness
- Poultry and poultry dishes: 541 outbreaks involving 16,280 cases of illness
- Beef and beef dishes: 467 outbreaks involving 13,220 cases of illness
- Eggs and egg dishes: 341 outbreaks involving 11,027 cases of illness

Multi-ingredient foods (such as salads, pizza, and sandwiches) where the contaminated ingredient was not identified were linked to 948 outbreaks and 27,812 cases of foodborne illness.

Foods regulated by the U.S. Food and Drug Administration (FDA), such as seafood, produce, eggs, and dairy, were associated with more than twice as many outbreaks as foods regulated by the U.S. Department of Agriculture (USDA), which include meats and poultry.

Recommendations
The Centers for Disease Control and Prevention (CDC) should continue to improve outbreak reporting and surveillance. The CDC has made improvements in its reporting and surveillance system, but gaps still remain. For example, nearly half of all states do not follow national standards to track disease outbreaks. Those gaps are particularly troubling, given current concerns about bioterrorism.

Congress should pass legislation to form a unified, independent food-safety agency with increased authority. Outbreaks occur, in part, because of inadequate regulatory authority, inadequate monitoring, and inadequate funding. Those problems will not be corrected until the underlying government structure is fixed. Congress needs to create a single food-safety agency, and to invest that agency with greater authority (such as the ability to recall food from the market and to penalize companies that produce contaminated products) than existing regulatory agencies have.
INTRODUCTION

In recent decades, changes in food production and consumption have impacted the safety of food. The food industry has evolved from being local to global, where production and processing are centralized in different parts of the country and world. Large-scale “farms” and feedlots can be breeding grounds for pathogens that are further dispersed in fast-paced slaughterhouses and processing plants. Additionally, large-scale processing can easily spread germs into large volumes of processed food, as evidenced by the September 2006 outbreak of *E. coli* 0157:H7 in prepackaged spinach which sickened over two hundred people across the country. Furthermore, some foodborne pathogens have become more virulent, while our population is aging and increasingly vulnerable to foodborne illness.

Unsafe foods cause an estimated 76 million illnesses and 5,000 deaths each year in the United States. Although people from all walks of life can develop foodborne illness, those who are most at risk include the elderly, young children, pregnant women and their fetuses, and the immunocompromised. While most illnesses occur as isolated cases, outbreaks of foodborne illness are clusters of illness that result from ingestion of a common contaminated food. A single outbreak can affect hundreds, or even thousands, of people.

Foodborne illness outbreaks are primarily investigated by state and local health departments. These local officials sometimes call on the federal Centers for Disease Control and Prevention (CDC) to help investigate large or multi-state outbreaks. The CDC is also responsible for nationwide surveillance of outbreaks and for tracking new and emerging pathogens. But many, perhaps most, outbreaks fall through the cracks because the states are not required by law to report foodborne illness outbreaks to the CDC.

In the United States, at least a dozen federal agencies have jurisdiction over some aspect of food-safety regulation. That highly fragmented system divides regulatory responsibility based on food products. However, the CDC’s system for reporting outbreaks does not synchronize easily with the regulatory system. Instead of emphasizing the foods that cause
outbreaks, the CDC’s lists of outbreaks are organized by pathogen and include outbreaks with unknown etiology and foods.

The primary agencies that inspect and regulate food are the United States Department of Agriculture (USDA), which oversees meat, poultry, and processed egg products, and the United States Food and Drug Administration (FDA), which oversees all other foods. Although FDA-regulated foods are linked to two-thirds of the outbreaks with known causes, the FDA’s budget is just 38 percent of the total federal budget for food safety. And while meat-processing plants are inspected by USDA daily, plants processing potentially contaminated seafood, eggs, lettuce, or processed foods containing less than two percent meat are inspected by FDA on average just once every five to ten years. When foodborne illness outbreaks do occur, neither the USDA nor the FDA has the power to order recalls of contaminated food. They must ask food companies to voluntarily remove foods from the market. The current system of voluntary recalls can delay the recall and increase the number of illnesses in an outbreak. Also, lawsuits brought by the meat industry have curbed USDA’s ability to close down plants producing contaminated meat. The regular occurrence of foodborne illness outbreaks in the United States today is evidence that the current food-safety system needs to be improved.

The Center for Science in the Public Interest (CSPI) has examined outbreaks linked to specific foods. Such data alert consumers to food-safety hazards, allow consumers to make informed risk decisions about the foods they eat, and provide better information to government for setting priorities for food-safety resource allocation. The findings presented here are from the 2006 Outbreak Alert! database, and are accompanied by a list of the most common foods associated with foodborne illness outbreaks, suggested food-safety interventions for each type of food, and CSPI’s recommendations for improving the safety of America’s food supply.
A DATABASE OF FOODBORNE ILLNESS OUTBREAKS

Data Collection

CSPI maintains a database of foodborne illness outbreaks, compiled largely from CDC and state health department annual outbreak line listings, reports by the CDC’s Foodborne Outbreak Response and Surveillance Unit, and peer-reviewed journal articles. Since 2001, CDC outbreak data for 1990-1998 and subsequent years have been available as yearly line listings on the Internet. Prior to 2001, the CDC outbreak data was unpublished, and obtained by CSPI via Freedom of Information Act requests. Additional outbreaks were obtained from scientific articles, federal government publications, state health department postings, and newspaper reports verified by public health officials; data from these additional sources constitute about 9% of the database. Each outbreak entry was assigned a reference number indicating the data source where the information was obtained.

Incidents of foodborne illness were only included in the CSPI database if they met the CDC’s definition of an outbreak: when two or more people have consumed the same contaminated food and come down with the same illness. In addition, each outbreak must have an identified etiology and food vehicle, must have occurred in the U.S. or its territories between 1990 and 2004, and must have been reported by a reliable source. Outbreak reports that met CSPI’s inclusion criteria were further evaluated to determine whether they were already listed in the database or whether they represented new outbreaks. Outbreak reports from different sources may contain slightly different information about the same outbreak. When such discrepancies were discovered, a public health official at the state, local, or federal level was contacted to determine which information was correct.

Excluded from the CSPI database were sporadic cases of foodborne illness.

Figure 3. Cases Linked to Outbreaks, 1990-2004
(individual cases not linked to an outbreak), outbreaks that had no identifiable etiology or food vehicle, and waterborne outbreaks.

**Food Categorization**

Each outbreak in the CSPI database was categorized by the implicated food, and the regulatory agency with primary responsibility for that particular food item. In general, meat, poultry, and processed egg products are regulated by the United States Department of Agriculture (USDA), while all other foods are regulated by the U.S. Food and Drug Administration (FDA). There are thirteen food categories in the CSPI categorization scheme, the majority of which were further divided into food subdivisions (see Appendix A).

Food categorization enables identification of the specific food-pathogen combinations causing large numbers of illnesses. Most reported foodborne illness outbreaks do not have complete outbreak information. In most years, 27 percent to 46 percent of outbreaks have no known etiology or vehicle. In addition, the majority of foodborne illness outbreaks go unreported due to their small size, long incubation period, geographic dispersion, an inability to identify the pathogen, or mild cases of illness which do not prompt individuals to seek medical care. For these reasons, the outbreaks included in the CSPI database represent only a small proportion of the actual foodborne illness outbreaks that occurred between 1990 and 2004.

**RESULTS**

**Overall Findings**

A total of 5,000 outbreaks, involving 152,097 cases of illness and occurring between 1990 and 2004, were included in the CSPI database. Nine percent of these outbreaks were from sources other than the CDC. The five food categories, excluding multi-ingredient foods, linked to the most foodborne illness outbreaks were seafood, produce, poultry, beef, and eggs. These five food categories were responsible for 59% of all outbreaks in CSPI’s database, and 54% of the cases. The produce category alone was linked to the largest number of foodborne illnesses associated with outbreaks, constituting 21% of all cases in CSPI’s database.
FDA-regulated foods were linked to 3,322 outbreaks with 93,221 cases, while USDA-regulated foods were linked to 1,345 outbreaks with 41,123 cases. Foods such as seafood, non-meat multi-ingredient foods, produce, eggs, dairy, breads, and beverages were linked to more than twice as many outbreaks and cases as meats and poultry. Outbreaks due to multiple foods, including both meat (USDA-regulated) and non-meat (FDA-regulated) items, comprised 7% of the database.

**FDA-Regulated Foods**

**Seafood and seafood dishes.** A total of 984 foodborne illness outbreaks with 9,969 cases were linked to seafood and seafood dishes. The average number of cases per seafood-linked outbreak was ten. Of the outbreaks associated with seafood, 622 outbreaks and 3,182 cases were linked to finfish such as tuna and grouper, and 155 outbreaks with 3,399 cases were linked to molluscan shellfish including oysters, clams, and mussels. Seafood dishes like crab cakes and tuna burgers were linked to 138 outbreaks with 2,516 cases. Other seafood, such as shrimp and lobster, were linked to 69 outbreaks with 872 cases. Hazards in seafood included scombrototoxin and ciguatoxin in finfish and *Vibrio* spp. and Noroviruses in shellfish. The majority of seafood outbreaks were caused by natural toxins, rather than by bacteria or viruses.
Multi-ingredient foods. A total of 948 foodborne illness outbreaks with 27,812 cases were linked to multi-ingredient foods. The average number of cases per multi-ingredient food outbreak was 29. Foods including rice, beans, stuffing, and pasta dishes were linked to 191 outbreaks and 4,696 cases. Multi-ingredient salads such as potato salad and coleslaw were linked to 215 outbreaks with 9,771 cases, while multi-ingredient sandwiches were linked to 129 outbreaks and 3,365 cases. Sauces, dressings, and oils caused 55 outbreaks with 1,875 cases. Multi-ingredient dishes, including lasagna, tacos, and lo mein, were associated with 223 outbreaks with 4,433 cases and 135 outbreaks and 3,672 cases were linked to other foods such as soups, puddings, and dips. *Salmonella* spp. and Noroviruses were the most common hazards associated with the multi-ingredient food category.

Produce and produce dishes. A total of 639 foodborne illness outbreaks involving 31,496 cases were linked to produce and produce dishes. The produce category had an average of 49 cases per outbreak. Vegetables were linked to 231 outbreaks with 11,957 cases, while fruits were identified as the vehicle in 103 outbreaks with 8,284 cases. Of the 103 fruit-associated outbreaks, 16 were linked to berries and 29 were linked to melon. Produce dishes were implicated in 305 outbreaks involving 11,255 cases. In produce-linked outbreaks, *Salmonella* spp., Noroviruses, and Escherichia accounted for the majority of foodborne illness cases.

**Figure 6. Vehicles of Produce-Related Outbreaks, 1990-2004**

Eggs and egg dishes. A total of 341 foodborne illness outbreaks with 11,027 cases were linked to eggs and egg dishes. The average number of cases per egg-linked outbreak was 32. Egg-based dishes such as french toast and egg salad were linked to 267 outbreaks with 8,910 cases, and eggs themselves were linked to 74 outbreaks with 2,117 cases. *Salmonella*
Enteritidis was the most common hazard among the egg-related outbreaks, accounting for 82 percent of the egg outbreaks.

**Dairy.** A total of 168 foodborne illness outbreaks and 5,580 cases were linked to dairy products such as cheese, milk, and ice cream. Dairy products had an average of 33 cases per outbreak. Milk was identified as the vehicle in 56 outbreaks with 1,457 cases, cheese was identified in 50 outbreaks with 1,791 cases, and ice cream was identified in 44 outbreaks with 1,807 cases. Unpasteurized items were associated with 30% of the dairy-related outbreaks. In outbreaks associated with dairy items, *Salmonella* spp. and *Campylobacter* spp. were the most common hazards.

**Breads and Bakery.** A total of 142 foodborne illness outbreaks with 4,136 cases were linked to breads and other bakery items. The bread and bakery category had an average of 29 cases per outbreak. Breads were associated with 32 outbreaks and 980 cases, while bakery items such as cake, pie, and cheesecake were linked to 110 outbreaks and 3,156 cases. *Salmonella* spp. and Noroviruses were the most common hazards in bread and bakery items.

**Beverages.** A total of 74 foodborne illness outbreaks and 3,015 cases were linked to beverages. The average number of cases per beverage-related outbreak was 41. Juices were associated with 22 outbreaks and 1,514 cases, among which almost a third were linked to unpasteurized juices. Other beverages such as alcoholic drinks, coffee, and soda were linked to 52 outbreaks with 1,501 cases. Contamination from chemicals, Noroviruses, *Salmonella* spp., and *E. coli* O157:H7 were the most common hazards in beverages.

**Game.** A total of 26 foodborne illness outbreaks with 186 cases were linked to game. This category includes walrus, bear, moose, venison, and cougar meats. The game category had an average of 7 cases per outbreak. In game-related outbreaks, the parasite *Trichinella* was the most common hazard.

**USDA-Regulated Foods**

**Poultry and poultry dishes.** A total of 541 foodborne illness outbreaks with 16,280 cases were linked to poultry. The average number of cases per poultry-related outbreak was 30. Chicken was linked to 214 outbreaks with 3,975 cases, while turkey was identified as the vehicle in 109 outbreaks with 5,832 cases. Seven outbreaks with 114 cases were linked to
other types of poultry, such as duck, game hen, and goose. Poultry dishes were linked to an additional 211 outbreaks with 6,359 cases. The most significant hazards in the poultry category were *Salmonella* spp., *Clostridium perfringens*, *Staphylococcus aureus*, and Noroviruses.

**Beef and beef dishes.** A total of 467 foodborne illness outbreaks with 13,220 cases were linked to beef. The average number of cases per beef-related outbreak was 28. Ground beef was linked to 171 outbreaks with 3,425 cases, while other types of beef such as roast beef, veal, and beef jerky were linked to 178 outbreaks with 6,439 cases. Beef dishes including casseroles, gravies, and stews caused 118 outbreaks with 3,356 cases. In beef-related outbreaks, the most common hazards were *E. coli* O157:H7, *Clostridium perfringens*, and *Salmonella* spp.

**Pork and pork dishes.** A total of 188 foodborne illness outbreaks with 6,081 cases were linked to pork. Ham was identified as the vehicle in 46 outbreaks with 2,107 cases. Other types of pork were linked to 112 outbreaks with 3,170 cases. Pork dishes were linked to 30 outbreaks with 804 illnesses. The pork category had an average of 32 cases per outbreak. The most common hazard in pork was *Staphylococcus aureus*.

**Luncheon and other meats.** A total of 149 foodborne illness outbreaks with 5,542 cases were linked to other meats. Of these, 50 outbreaks with 1,014 cases were attributed to hot dogs and other ready-to-eat luncheon meats such as bologna and salami. Thirty-six outbreaks with 2,193 cases were linked to other meats including lamb, goat, and sausage. Meat dishes were linked to 63 outbreaks with 2,335 cases. The other meats category
had an average of 37 cases per outbreak. *Clostridium perfringens* was the most common hazard for outbreaks linked to other meats.

**Foods Regulated by Both FDA and USDA**

*Multiple foods.* A total of 333 foodborne illness outbreaks with 17,753 cases were linked to meals containing foods regulated by both FDA and USDA. These foods included such meals as chicken served with salad, pork with coleslaw, and ground beef with potatoes. This category had an average of 53 cases per outbreak. In foods regulated by both the FDA and USDA, *Salmonella* was the most common hazard.

**FOODS MOST FREQUENTLY LINKED TO FOODBORNE ILLNESS OUTBREAKS**

*Produce*

Although diets rich in fruits and vegetables provide clear health benefits, those foods occasionally carry harmful microorganisms, including *Salmonella*, Noroviruses, and *E. coli*. Pathogens can jump from animals to produce via contaminated irrigation water, direct application of inadequately processed manure to soil, or even cross-contamination from raw meats in the kitchen. In fact, approximately 30 percent of the produce outbreaks identified by CSPI were caused by pathogens commonly found in meat and poultry. Viruses, like Norovirus and Hepatitis A, often are transferred to produce from human sources. Pathogens can adhere to the rough surfaces of fruits and vegetables, so consumers should take precautions, such as washing produce under running water. Despite the risk, consumers should still eat plenty of fruits and vegetables. But with mandatory farm-based controls, consumers could enjoy the benefits of raw produce with less risk of foodborne illness.

In September 2006, tainted prepackaged Natural Selections spinach triggered an *E. coli* O157:H7 outbreak resulting in at least three deaths and 204 illnesses. The spinach was traced back to Salinas Valley, California, where samples of cattle feces found near a field that produced the
contaminated spinach matched the genetic pattern of the strain of *E. coli* found in the people who became ill.\textsuperscript{15}

Soon after the September spinach outbreak, consumers were sickened with a different hazard – *Salmonella* Typhimurium, found in tomatoes. In September and October 2006, over 183 people in 21 states became ill from *Salmonella*-contaminated tomatoes served in restaurants. Minnesota, Massachusetts, Kentucky, and Connecticut had large numbers of infected consumers.\textsuperscript{16}

**Seafood**

Seafood is one of the leading causes of food-borne illness outbreaks in the U.S. Outbreaks can result from naturally occurring toxins, such as scombrototoxin and ciguatoxin in finfish, and microbial hazards, such as *Vibrio* bacteria and Noroviruses, in shellfish. In finfish, harvesting conditions or improper handling after harvest can cause toxins to form. Once formed, the toxins are not destroyed by cooking.\textsuperscript{17} Shellfish can become contaminated with bacteria and viruses in harvesting beds. If not refrigerated shortly after harvest, levels of pathogens can increase. For example, the deadly bacterium *Vibrio vulnificus* can grow in shellfish to numbers 10 to 100 times higher over several hours if the shellfish are not refrigerated after harvest.\textsuperscript{18}

![Figure 9. Leading Seafood Pathogens](image)

To help keep seafood safe, the FDA should increase its inspection of processors and implement testing programs to verify that firms are controlling the hazards in their products. Consumers can help protect themselves by not eating tropical or subtropical reef fish like barracuda, by refrigerating all seafood, and by only eating cooked shellfish or raw shellfish that have been treated to eliminate hazardous bacteria.

**Poultry**

Hazards commonly linked to poultry outbreaks include *Salmonella* spp., *Clostridium perfringens*, and *Staphylococcus aureus*. *Campylobacter jejuni* is a hazard frequently associated with raw poultry, however
virtually all illnesses occur as sporadic cases and not as part of large outbreaks. Thus, the effects of that pathogen are not captured in outbreak data. Farm practices, such as crowding and the use of antibiotics, also can affect the safety of poultry products. Farmers and processors must recognize the critical role they play in maintaining a safe food supply. Government food-safety programs should be expanded to improve conditions on farms, as well as in the slaughtering plants.

During the summer of 2002, an outbreak of *Listeria monocytogenes* caused over 120 illnesses and 13 deaths. In the aftermath of that outbreak, Wampler Foods recalled 27.4 million pounds of fresh and processed poultry products, making this one of the largest recalls in history. Consumers can decrease the risk from contaminated poultry by avoiding cross-contamination when handling raw poultry and by cooking all poultry thoroughly.

**Beef**

*E. coli* O157:H7 and *Clostridium* spp. are the biggest hazards in beef. These bacteria live in the intestines of animals without causing illness to the animal, but can cause diarrhea, vomiting, painful abdominal cramps, and sometimes kidney failure and death if ingested by humans. Many beef outbreaks listed in *Outbreak Alert!* might have been avoided if the government and the beef industry were more vigilant about keeping hazards out of meat, and increased their testing of beef products. Consumers can help protect themselves by cooking all beef to 160°F, using a meat thermometer to verify temperature, to ensure all bacteria are killed.

Beef and beef dishes have caused many large, well-publicized outbreaks of foodborne illness and recalls. In September 2004, an outbreak of *Salmonella* Typhimurium resulted in 31 illnesses in nine states. An investigation conducted by state health departments, CDC, and the USDA Food Safety and Inspection Service (FSIS) identified ground beef
purchased at a national chain of supermarkets as the source of S. Typhimurium infections. Traceback results found that the product originated from a common supplier; however, plant practices conformed to FSIS production guidelines, and no product recalls were made. Without recalls, tainted meat can continue to be sold at supermarkets, served at countless restaurants, and grilled at homes.20

**Eggs**

Eggs and egg dishes cause large numbers of outbreaks every year. The primary hazard associated with the consumption of raw and undercooked eggs is *Salmonella* Enteritidis (SE), which caused 96% of outbreaks in eggs. In 1998, the USDA estimated that approximately one egg in 20,000, or about 2.3 million eggs annually, contained SE.21 To better protect consumers, FDA should finalize plans to increase oversight on the farm, including ensuring that chicken flocks are tested for SE, increased immunization of flocks, and ensuring that eggs from SE-contaminated flocks are pasteurized prior to sale. In the meantime, consumers can protect themselves by fully cooking eggs and egg dishes; by avoiding foods containing raw eggs, such as Hollandaise sauce and raw cookie dough; or by using pasteurized eggs.

**Multi-Ingredient Foods**

Multi-ingredient foods, including pizza, salads, and sandwiches, cause a large number of outbreaks. Pathogens of concern include Noroviruses and *Salmonella*. Many practices in home and restaurant kitchens can make multi-ingredient foods hazardous, including cross-contamination, under-cooking, inadequate cooling and storage, and worker contamination. Some states and counties have adopted grading systems to inform consumers about restaurants’ compliance with health codes and to encourage restaurants to improve their practices. At home, consumers can protect themselves by cleaning all cutting boards, utensils, hands, and other surfaces that touch raw meat before using them to prepare or serve other foods; by cooking foods thoroughly; and by refrigerating leftovers promptly.
RECOMMENDATIONS

With the continuing occurrence of foodborne illnesses and more recent concerns about bioterrorism, bovine spongiform encephalopathy, and avian influenza, changes are needed in government systems to increase public health protections. Implementing the following recommendations would help close holes in the federal food-safety net and, ultimately, decrease the number of illnesses and deaths caused by contaminated food.

The CDC Should Continue To Improve Outbreak Reporting and Surveillance

Outbreak information serves several important functions. It can alert consumers to food safety hazards and help policymakers and public health officials to (1) identify emerging problems, (2) evaluate existing programs, and (3) set goals and priorities for food safety. Having a timely and comprehensive inventory of foodborne illness outbreaks would allow food regulators to monitor trends, issue consumer alerts, and improve production practices. Historically, the CDC’s foodborne illness outbreak reporting and surveillance programs have fallen short of meeting those goals, but in the past several years, CDC has made several improvements.

- The CDC has dramatically increased its use of the Internet to gather foodborne illness outbreak reports. The agency’s website offers state public health officials an outbreak investigation tool kit and online reporting forms.

- The CDC has resumed publishing its line listing of foodborne illness outbreaks, a practice that was ended in the mid-1980s due to funding constraints. The CDC has published new outbreak information on its website, including line listings for 2004.

- Reporting by the states has also increased. As a result, the CDC updated its line listings for 1990-1997 to include over 500 outbreaks that were not on the older version of the listings.

- The CDC has expanded systems such as FoodNet and PulseNet, which provide information needed for faster nationwide tracking of foodborne illness.

Those improvements are important, but the CDC also should mandate reporting by states, provide real-time reporting of outbreaks, and organize
outbreaks by food hazard to increase the utility of its information. Those gaps are particularly troubling, given the threat of bioterrorism to our food supply.

While better monitoring and reporting of foodborne illness outbreaks are important, the most important goal is to develop a preventative system that reduces the toll of foodborne illnesses.

*The Recipe for Safe Food: A Unified, Independent Food-Safety Agency*
Currently, food is regulated by at least a dozen different federal agencies and 35 different statutes. A single, independent food-safety agency – administering a unified statute – could better address the problems with food-safety inspection and regulation, including gaps in consumer protections, inadequate coordination, conflicting public health standards, regulatory redundancies, and slow approvals of new technologies. A strengthened food-safety net should help decrease the numbers of foodborne illnesses and provide better protection against bioterrorism. A 1998 Institute of Medicine (IOM) report on food safety called for the consolidation of food-safety responsibilities under a single statute, with a single budget and single leader. The IOM report concluded that the “current fragmented regulatory structure is not well equipped to meet the current challenges.”24 In October 2001, the General Accounting Office reported that:

> A single food-safety agency responsible for administering a uniform set of laws is needed to resolve the long-standing problems with the current system; deal with emerging food-safety issues, such as the safety of genetically modified foods or deliberate acts of contamination; and ensure a safe food supply.25

The transition to a new and more effective federal agency offering more comprehensive protections to public health requires both organizational and statutory changes.
**Organizational Changes**

The Bush Administration and Congress should unify all of the federal food-safety activities within a single, independent agency – the Food Safety Administration (FSA). Legislation to create a unified agency has been introduced in Congress by Senator Richard Durbin (D-IL) and Representative Rosa DeLauro (D, 3rd-CT). That agency would be responsible for setting food-safety and labeling standards, approving new food technologies, conducting food-safety inspections, and enforcing the relevant laws. A presidentially appointed, congressionally confirmed Administrator should lead the new agency. The FSA should integrate units from numerous federal departments, including:

- USDA’s Food Safety and Inspection Service and the egg inspection program of USDA’s Agricultural Marketing Service;
- FDA’s food regulatory components (including the Center for Food Safety and Applied Nutrition, components of the Center for Veterinary Medicine, and the food-related laboratory and field resources of FDA’s Office of Regulatory Affairs);
- Environmental Protection Agency’s pesticide tolerance setting program; and
- Department of Commerce’s voluntary seafood inspection program.

The non-regulatory, foodborne illness surveillance program of the CDC should remain separate to provide ongoing information on the nature and magnitude of food-safety hazards. Similarly, food-safety research activities conducted by the National Institutes of Health, Agricultural Research Service, and other research agencies should not be incorporated into the FSA, but should provide research responsive to the needs of that agency.

**Statutory Changes**

The food-safety and inspection provisions of the Federal Food, Drug and Cosmetic Act, the Federal Meat Inspection Act, the Poultry Products Inspection Act, and the Egg Products Inspection Act need to be replaced by a unified and modernized food-safety statute. The new statute would

---

“A single food safety agency is the single best way to protect families from food-related illness or attack.”

- Sen. Dick Durbin (D-IL), co-chair of the Congressional Food Safety Caucus

---
build on the strengths of the existing laws, while modernizing the mandates and authorities of the new FSA. The unification of the food-safety system should be accomplished over several years, with full participation by many stakeholders, including the food and agriculture industries, scientists, and public health experts. Key elements would include:

**Clear definition and empowerment of the roles of government, consumers, and the food industry,** including: (1) the food industry’s responsibility to produce safe products by using up-to-date preventive process controls; (2) the government’s authority to establish and oversee compliance with food-safety standards, such as limits on pesticide residues and performance standards for reducing microbial pathogens; (3) the government’s responsibility to use its regulatory tools in ways that systematically reduce the risk of foodborne illness; and (4) consumers’ right to transparent government decision-making and accountability.\(^\text{27}\)

**A modernized mandate for food inspection to:** (1) require that inspection resources be allocated across the food supply based on risk; (2) set a minimum frequency of inspection for food-production establishments, taking into account the food-safety risks and companies’ past performances; (3) establish a statutory mechanism to ensure that inspection resources are increased as needed to allow for risk-based reallocation and that future funding levels are adequate to meet the modernized inspection mandate; and (4) coordinate inspections and resource allocation with state and local food-safety agencies.

**Enhancement of enforcement authorities and other tools of accountability,** including: (1) authority to mandate recalls of contaminated food; (2) adequate civil and other penalties for repeat or egregious violators of food-safety standards; and (3) citizen-suit provisions to enforce food-safety statutes.

**Strengthened oversight of imported foods to ensure they are at least as safe as U.S.-produced foods,** including: (1) authority to ensure that imported foods meet U.S. safety standards; (2) increased inspection of foreign food-production establishments, especially in countries whose food-safety regulatory systems have not been demonstrated to be equivalent to the U.S. system; and (3) increased border inspections of imported food.
Refinement of the procedures for evaluating and approving new food technologies, for example, carcass treatments to reduce bacteria, in order to: (1) maintain high scientific standards; (2) increase opportunities for public participation; (3) expedite the availability of technologies that can improve food safety.

A mandate to regulate animal production practices that cause or contribute to human illness, including (1) the authority to require feedlots, factory farms, and other producers to raise and transport livestock in ways that prevent or minimize pathogen contamination; and (2) a broad mandate to address the misuse and overuse of antibiotics in livestock production.

While creating a single food-safety agency with new authorities must be done thoughtfully, it also must be done expeditiously. Gaps in current systems are leaving consumers vulnerable to outbreaks of foodborne illness from both bioterrorism and unintentional contamination. Consumers cannot afford to wait years or even decades for the agencies to resolve their competing agendas. It is time for the government to enhance CDC programs and create a single food-safety agency that enforces a modernized and unified food-safety statute.
### APPENDIX A: SUMMARY OF FOODBORNE OUTBREAKS AND CASES, 1990-2004

#### FDA-Regulated Foods

ENDNOTES

3 The terms “food poisoning” and “foodborne disease” are often used interchangeably. However, the term “foodborne disease” reflects three kinds of causes: foodborne intoxications (from ingestion of foodborne poisons); foodborne infections (caused by foodborne pathogenic microorganisms such as Salmonella that, when ingested, cause infections); and foodborne toxicoinfections (from foodborne pathogens such as E. coli O157:H7 that, once ingested, produce harmful toxins). Satin M. Food Alert! The Ultimate Sourcebook for Food Safety. New York: Checkmark Books; 1999. p.16-17.

9 Centers for Disease Control and Prevention. Foodborne illness: general information. Last accessed on November 30, 2006 at <http://www.cdc.gov/ncidod/dbmd/diseaseinfo/foodborneinfections_g.htm#whato utbreak>. Before 1992, the exception to this rule was botulism where one illness was considered an outbreak. After 1992, the CDC started omitting outbreaks of botulism with only one case from its line listings. CSPI’s database reflects these changes.

10 The CDC’s U.S. Foodborne Disease Outbreaks, 1990-2003 contained over 7,000 outbreaks with unknown etiology or food vehicle that were not included in CSPI’s database. Outbreaks were included in CSPI’s database if a suspected vehicle was identified.

Pathogens with animal reservoirs include *Salmonella* spp., *E. coli*, *Campylobacter* spp., and *Yersinia* spp.

In July 2002, there was a 19 million pound recall and at least 38 illnesses due to *E. coli* O157:H7 in ground beef.

Telephone conversation with Dr. Patricia Griffin, Chief of Foodborne Diseases, Foodborne and Diarrheal Branch, Division of Bacterial and Mycotic Diseases, National Center for Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, GA, January 14, 1999.

CSPI obtained the older, unpublished version of the 1990-1997 line listings by submitting a Freedom of Information (FOIA) request to the CDC.

27 Although foodborne illness victims and their families can sue food firms for product liability, most do not because of the difficulty of linking the illness to a definitive food source, according to the U.S. Department of Agriculture’s Economic Research Service. Jean C. Buzby et al., Economic Research Service, Product Liability and Microbial Foodborne Illness 24 (2001). Citizen suits, in which citizens or citizen groups sue firms that violate laws or regulations, might be a more effective remedy. Such provisions also allow citizens to sue the government for neglect of certain duties. While the major environmental statutes (including the Clean Water Act, 33 U.S.C. §1365) authorize citizen suits, none of the food laws contain such provisions.
